## Abstract

Mucormycosis is an invasive fungal infection associated with a high mortality rate, especially in immunocompromised hosts. Mucormycosis rarely occurred in cirrhotic patients. We reported a mucormycosis case with underlying diseases of liver cirrhosis and diabetes mellitus. This case suffered from maxillary sinusitis and osteomyelitis and was successfully treated by surgical debridement, antifungal agents including amphotericin B, itraconazole, and posaconazole, subsequently, and hyperbaric oxygen therapy. It is a first report for posaconazole in the treatment of mucormycosis in a cirrhotic patient that revealed safety and efficiency.
