Abstract: Phlebosclerotic colitis is a rare type of ischemic colitis, characterized by thickening of the wall of the right hemicolon with calcification of mesenteric veins. Its etiology remains unknown but may be probably ingested toxic agent-related. We herein report a 51-year-old woman presenting with intermittent peri-umbilical abdominal pain for 1 week. Physical examination revealed a distended abdomen with diffuse tympanic sounds on percussion. Laboratory data revealed non-specific findings except leukocytosis. KUB film showed linear calcifications along the right side of the abdomen. Abdominal computed tomography revealed bowel wall thickening from splenic flexure colon to ascending colon. Colonoscopy demonstrated brownish-black pigmentation on the right side of the colon with scattered hyperemic patches. Idiopathic mesenteric phlebosclerosis (IMP) was impressed accordingly. She finally underwent surgical resection of diseased colon because of medical refractories.
