A 60-year-old male has no systemic disease before. He was admitted to our hospital under the impression of hepatitis, and finally diagnosed with a disease of hemophagocytosis after serial examinations. High doses of systemic steroid, Etoposide (VP-16) and Rituximab were administered. On the third day of Rituximab injection, he had a spike fever, epigastric pain and persisted vomit. *Bacillus cereus* bacteremia was noted. He was successfully treated with early intravenous treatment with vancomycin, and Imipenem / Cilastatin. *B. cereus* bacteremia is not common, but it may occur in immuno-compromised individuals, such as those post immune suppressive medications.
