Abstract:

This 36-year-old male was admitted with the chief complaint of diarrhea. Colonoscopy was unrevealing. Upper endoscopy was undertaken that showed negative finding. He was proceeded with jejunoscopy evaluation. A marginal ulcer was noted in proximal jejunum. Pathology report of biopsy showed compatible result with enteropathy associated T cell lymphoma. He received surgical intervention twice and five cycles of chemotherapy despite of the progression of disease. Left sided hemiplegia and consciousness disturbance was noted 9 month later. CT of brain was conducted that showed mass lesion over bilateral frontal lobes and corpus callosum which was suggestive of brain metastasis of lymphoma. Family opted for hospice care and patient expired shortly after discharge. Further review of enteropathy associated T cell lymphoma and brain metastasis were discussed.
