Abstract:

Hepatocellular carcinoma (HCC) accounts for the majority of primary liver cancer and is the fourth leading cause of cancer-related death worldwide. Despite the promotion of regular surveillance and hepatitis B vaccination, a large number of cases are still at an advanced stage with macrovascular invasion or extrahepatic metastasis. Extra-hepatic metastases of HCC are often observed in lungs, lymph nodes, bones, adrenal glands, and brain. However, some unusual metastatic sites could be noted and would lead to misdiagnosis in the clinical practice.
